Gas Turbine Operation, Performance, Maintenance and Repair Training Course

Introduction

Introduction

Gas turbines are internal combustion engines in which the burning of an air-fuel mixture produces hot gases that spin a turbine to generate power. It is the process of hot gas production during fuel combustion. Basic operation of gas turbines is called the Brayton cycle.

They are used to power aircraft, trains, ships, electric generators, pumps, etc. It is advantageous to use gas turbines for power generation because they have a high power-to-weight ratio, are smaller than most other engines, show smooth main shaft rotation, are more reliable, have lower peak combustion pressures, etc.

Their regular maintenance is extremely critical because it increases system efficiency, extends life-cycle of the turbine, reduces maintenance costs, etc.

This Xcelerate Training Institute course will empower you with detailed knowledge and understanding of gas turbines, including their operation, performance, maintenance and troubleshooting.

Through this course, you will build your skill set to cater to all aspects concerning gas turbines, a pre-requisite for senior roles in processes involving gas turbine operations. This course will prepare you to undertake higher roles and responsibilities not just in your organization but any other organization.
